# Phototrophic symbioses

- Generally macroscopic hosts nutritionally dependent on microscopic endosymbionts providing organic carbon produced by the photosynthesis

# Phototrophic symbioses

- Lichens

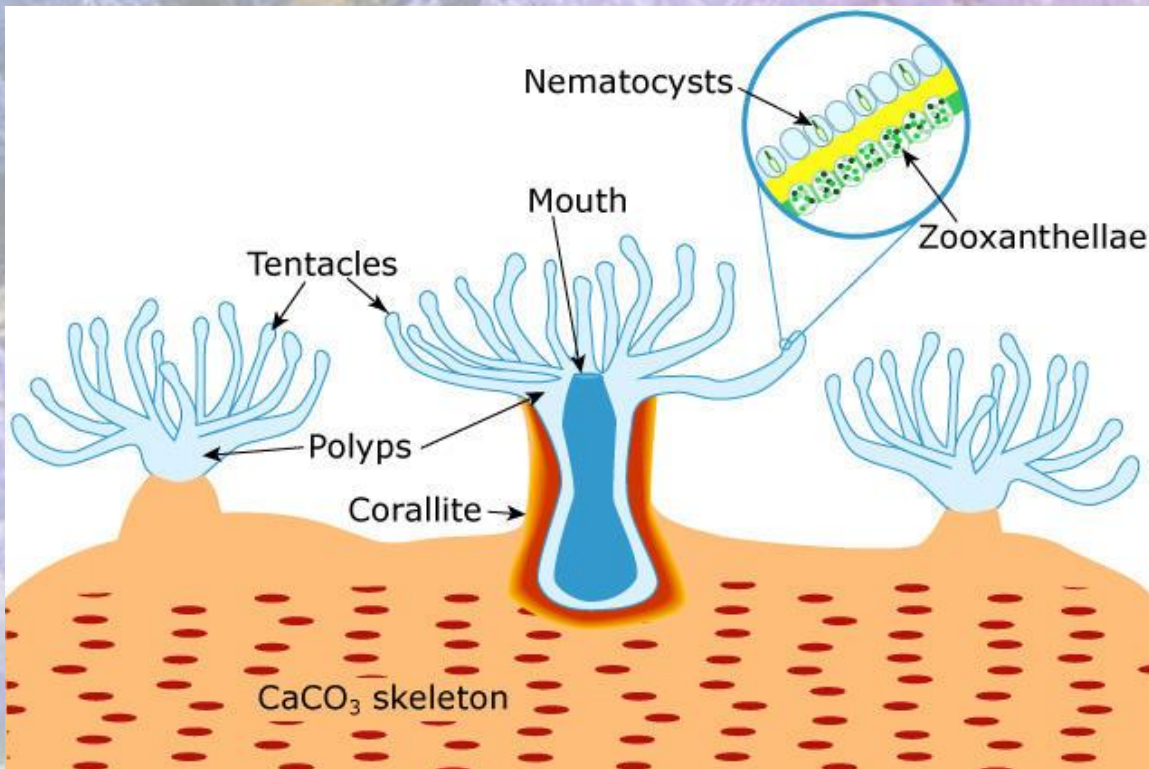

- Dominate 8% of the Earth's land surface
- Impacting global fluxes of carbon and nutrients
- Soil stabilization and development

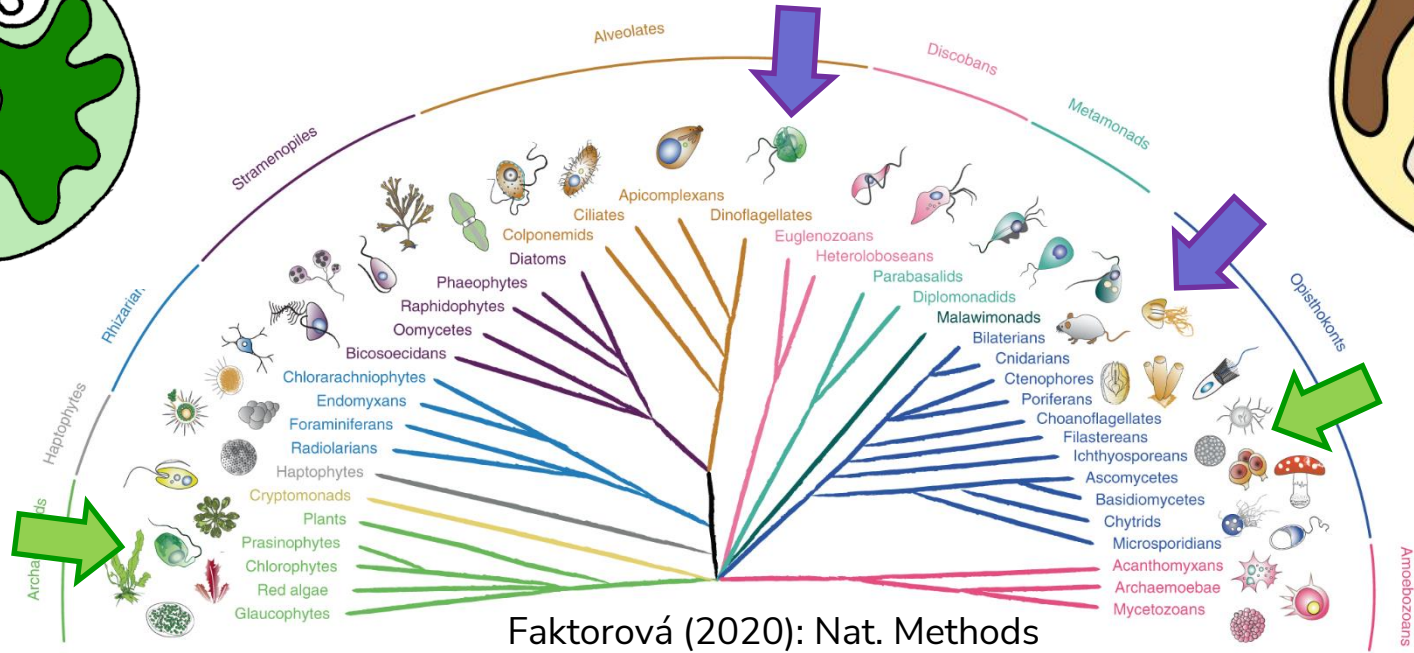

# Phototrophic symbioses

- Corals

- Cover 0.17% of the ocean surface
- Coral reefs as important planetary biodiversity hotspots

# Phototrophic symbioses

# Horizontal transmission

- The majority of heterotrophic hosts disperse without their symbionts by sexually propagated offspring, and thus have to re-establish the symbiotic state at each reproductive cycle

# Horizontal transmission

- The majority of heterotrophic hosts disperse without their symbionts by sexually propagated offspring, and thus have to re-establish the symbiotic state at each reproductive cycle

# Vertical transmission

- Co-dispersal of both symbionts

# Enormous disparity in species richness

- Lichens:

- ~ 17,000 host species
- ~ 233 algal symbiotic lineages

- Corals:

- ~ 6,000 host species
- ~ 200 algal symbiotic lineages

lichens

corals

■ hosts

■ algal symbionts

# High specialization of symbionts

- Strong algal host specificity

Bongaerts et al. (2013) BMC Evol. Biol.

C - Habitats

'Back Reef' (~2 m)

'Upper Slope' (~6 m)

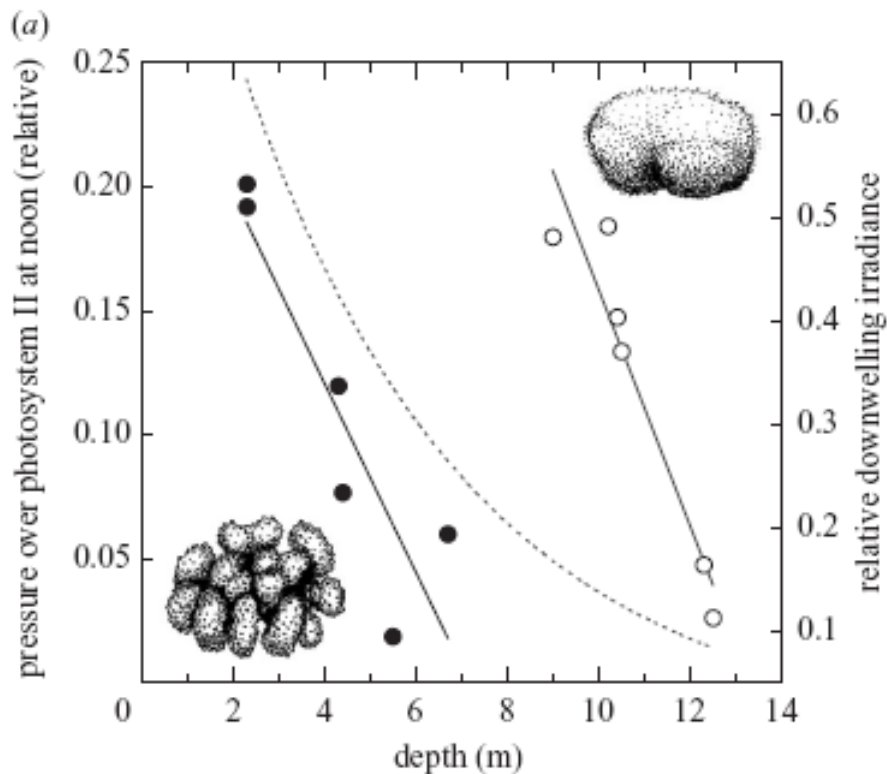

'Deep Slope' (~27 m)

Bongaerts et al. (2010) Plos ONE

# High specialization of symbionts

- Narrow ecological niches of algal symbionts

*Pocillopora*

*Pavona*

# High specialization of symbionts

Boulotte et al. (2016): ISME J

# Habitat adapted symbiosis

# Habitat adapted symbiosis

- Core species (vertical transmission) act as symbiont distributors for fringe species (horizontal transmission)
- A widely adopted concept in cyanolichens. What about green algae?

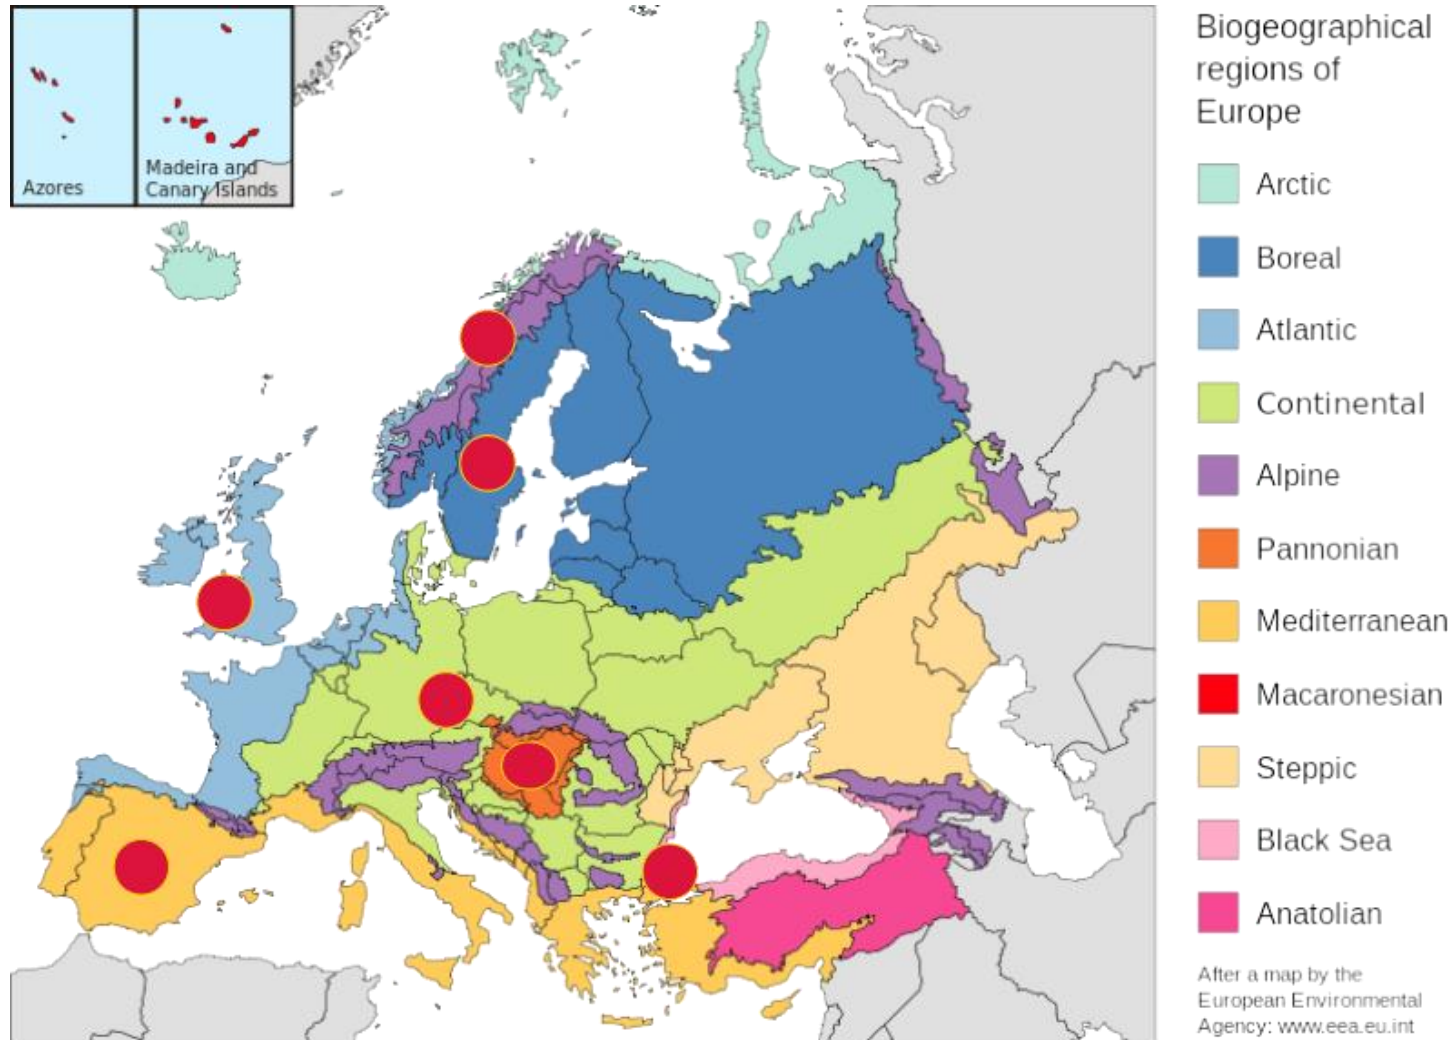

# Lichen guilds

*Cladonia*

- Which factors shape the associations between the lichen symbiotic partners?

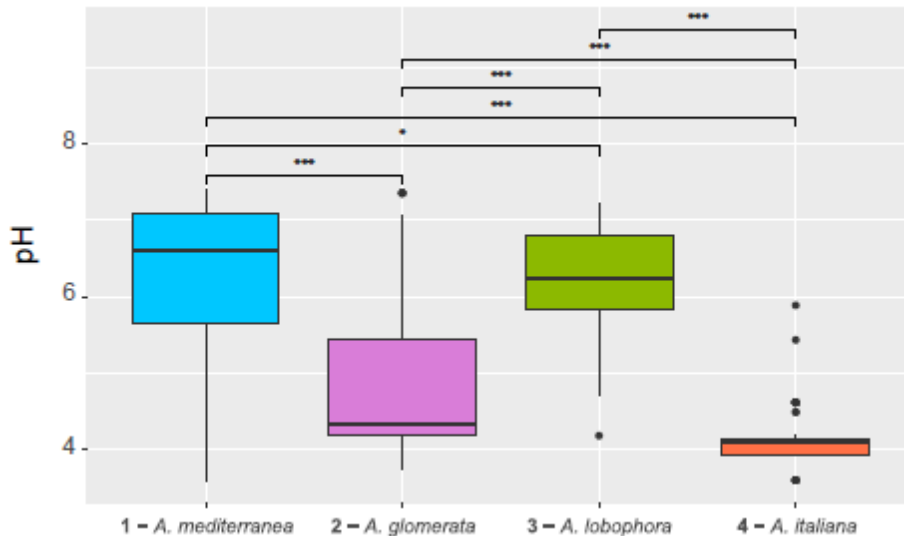

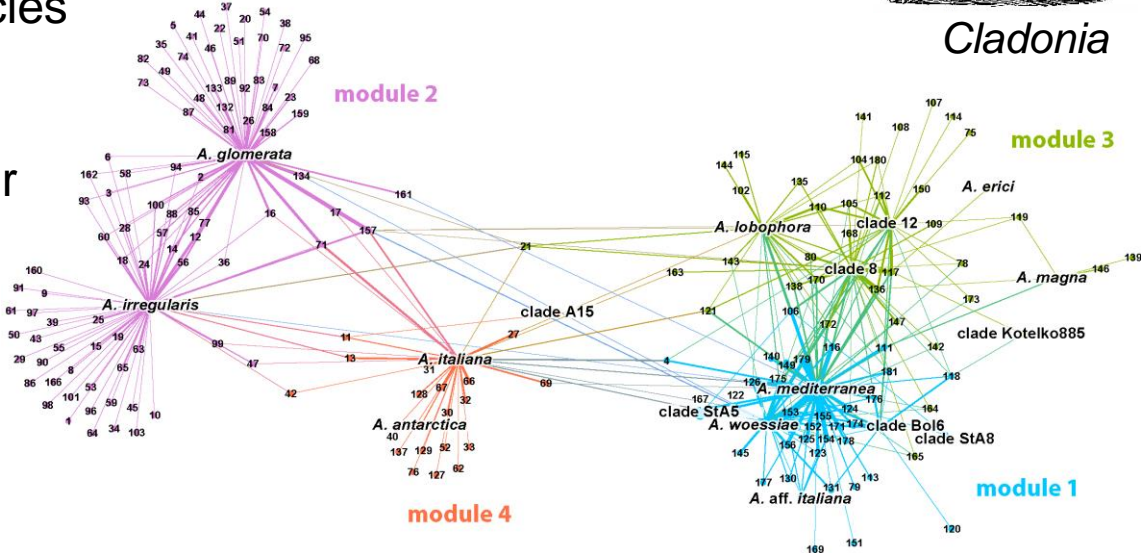

# Lichen guilds

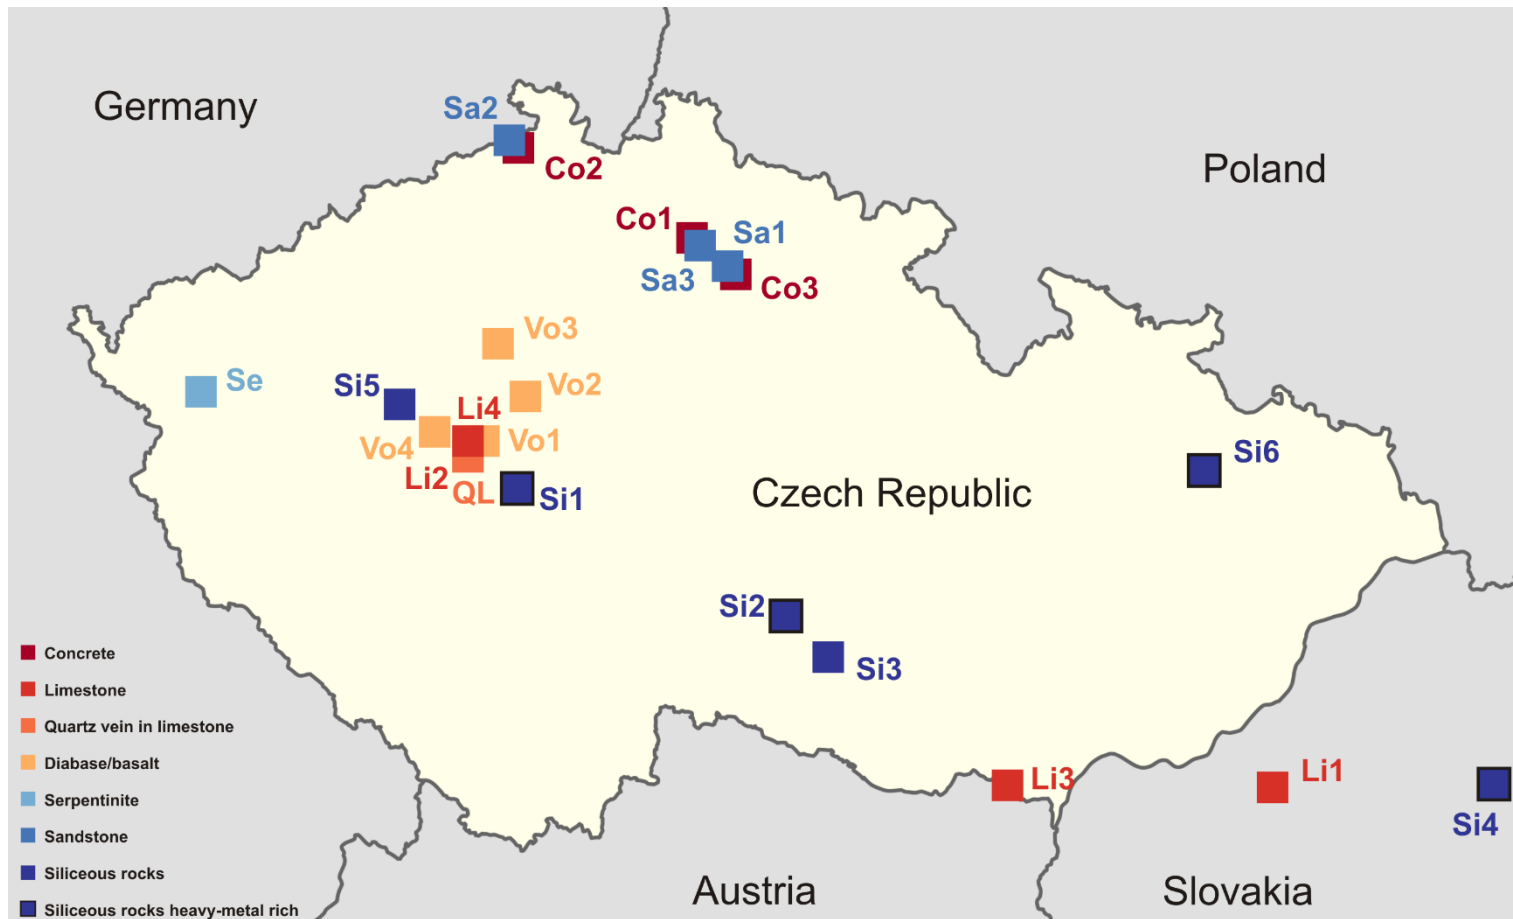

*Cladonia*

- The host choice of the symbiotic partner is limited to those species belonging to the same guild
- The guilds can be clearly distinguished according to their preferences for soil chemistry and climatic conditions
- Fungi therefore have only a limited ability to increase their ecological niche through algal switching

# Lichen guilds

- Do green algal lichens form the guilds mediated by photobionts?
- Do lichens reproducing by symbiotic propagules (core species) fulfil the role of photobiont distributors in mycobiont assemblages?
- *22 saxicolous lichen communities, 250 sequenced lichen photobionts*

# Lichen guilds

- The fungal assemblages exhibited distribution influenced by photobionts which formed three clearly separated groups
- Three photobiont-mediated guilds were detected, conditioned by substrate chemistry (pH).

Detrended correspondence analysis (DCA) of saxicolous lichen communities with three main rock types highlighted in color. A network of photobiont-mycobion associations is visualized.

# Symbiont acquisition

- Symbiosis dynamics on river gravel bars
- Selected plots - sequencing all endosymbiotic and free-living algae
- **Host symbionts are physically absent in the environment**

A. Roseg Valley, Switzerland  
**Stereocaulon**

# Symbiont acquisition

- How do hosts acquire their symbionts from environment?
  - Young lichen hosts are extremely unspecific towards their symbionts, their hyphae even encircle glass beads in the same manner as algal cells

Ahmadjian & Jacobs (1981): Nature

Sanders et al. (2014): Am. J. Bot.

# Symbiont acquisition

- How do hosts acquire their symbionts from environment?
  - Young corals may attract algal symbionts by emitting green fluorescence under daylight conditions (strong blue light), using GFP

# Conclusions

- Lichens and corals are unexpectedly similar in their nature of symbiotic interactions
- The guilds of lichens are shaped by substrate chemistry (pH)
- The fungal hosts are frequently forming symbiotic associations with algal partners, which are
  - physically absent in the environment
  - not co-dispersed with their host
  - absent in co-occurring vertically-dispersed lichens (so called core species)
